INVESTIGATING THE STRUCTURE OF $M_2(\mathbb{F}_q)$

IAN GALLAGHER
DR. ERIC BRUSSEL

ABSTRACT. We present and prove a count of the maximal commutative sub-algebras of $M_2(\mathbb{F}_q)$, as well as counts for the individual isomorphism classes.

1. INTRODUCTION

For a finite field of $q = p^m$ elements, $p \neq 2$, it is possible to count the number of vector subspaces of $\mathbb{F}_q{}^n$ of a given dimension. These counts arise in problems involving the number of points of $\mathbb{P}_q^n$, the Grassmannian, and further generalizations.

This paper is meant to address a similar problem. Namely, the structure and count of the maximal commutative sub-algebras of $M_2(\mathbb{F}_q)$. Such sub-algebra's...

2. GENERALIZED QUATERNIONS AND $M_2(\mathbb{F}_q)$

For the duration of the paper, $q = p^n$ for some prime $p \neq 2$.

Definition 1 (Generalized Quaternions). Let k be a field, char $k \neq 2$, and fix $a, b \in k - \{0\}$. Then the *generalized quaternions* are a central simple k-algebra (CSA) of the form

$$A_{a,b}(k) = \{t + xi + yj + zl : t, x, y, z \in k\}$$
$$\text{where } i^2 = a, j^2 = b, \text{ and } ij = -ji = l$$

Definition 2 (Generalized Quaternions, Vector Notation).

$$A_{a,b}(k) = \{(t, \mathbf{v}) : t \in k, \mathbf{v} = \langle xi + yj + zl \rangle, x, y, z \in k\}$$
$$\text{where } i^2 = a, j^2 = b, \text{ and } ij = -ji = l$$

Definition 3 (Generalized Quaternion Norm).

$$N_{a,b} : A_{a,b}(k) \to k$$
$$q \mapsto q\bar{q} = t^2 - ax^2 - by^2 + abz^2$$

Theorem 4 (Wedderburn). *requires citation Let k be a field and A a central simple algebra. Then $A \simeq M_n(D)$ for some k-division algebra D.*

Theorem 5 (Chevalley-Warning). *requires citation Let $f_\alpha \in \mathbb{F}_q[X_1, \ldots, X_n]$ be polynomials in n variables such that $\sum_\alpha \deg f_\alpha < n$ and let V be the set of their common zeros in $\mathbb{F}_q^n$. One has*

$$|V| \equiv 0 \pmod{p}$$

Lemma 6. *$N_{a,b}(X)$ has a nontrivial zero over $A_{a,b}(\mathbb{F}_q)$.*

Date: June 3, 2021.

Proof. TBD   □

Theorem 7. $A_{a,b}(\mathbb{F}_q) \cong M_2(\mathbb{F}_q)$

3. PLANES IN $M_2(\mathbb{F}_q)$

For a matrix $A \in M_2(\mathbb{F}_q)$, we know

(1) A's characteristic polynomial: $p_A(X) = X^2 - \mathrm{tr}(A)X + \det(A)$.
(2) A's minimum polynomial: $m_A(X) = X - A$ if $A \in \mathbb{F}_q$. Otherwise, $m_A(X) = p_A(X)$.

This gives an evaluation map $\epsilon_A : \mathbb{F}_q[X] \to M_2(\mathbb{F}_q)$ taking $f(X)$ to $f(A)$, which is a $\mathbb{F}_q$-linear ring homomorphism with image $\mathbb{F}_q[A] \subseteq M_2(\mathbb{F}_q)$. The kernel is nontrivial, since $M_2(\mathbb{F}_q)$ has finite $\mathbb{F}_q$-dimension and $\mathbb{F}_q[X]$ does not. It follows that $ker(\epsilon_A) = (m_A(X))$. By the First Isomorphism Theorem,

$$\frac{\mathbb{F}_q[X]}{(m_A(X))} \cong \mathbb{F}_q[A]$$

So if $A \in M_2(\mathbb{F}_q) - \mathbb{F}_q$, we know $m_A(X) = p_A(X)$ is degree 2 and $\mathbb{F}_q[A]$ has $\mathbb{F}_q$-dimension 2.

Thus, we have that each such A generates the unique 2 dimensional commutative sub-algebra of $M_2(\mathbb{F}_q)$ containing A. All possible 2 dimensional commutative sub-algebra's are therefore of the form

$$\frac{\mathbb{F}_q[X]}{(m_A(X))}$$

for some $A \in M_2(\mathbb{F}_q) - \mathbb{F}_q$. The set of two dimensional commutative sub-algebra's of $M_2(\mathbb{F}_q)$ must then be composed of exactly three isomorphism classes based on $m_A(X)$

(1) If $m_A(X)$ is irreducible, then $\mathbb{F}_q[A] \cong \mathbb{F}_{q^2}$
(2) If $m_A(X)$ is reducible but not separable, then $\mathbb{F}_q[A] \cong \mathbb{F}_q \times \mathbb{F}_q$
(3) If $m_A(X)$ is separable, then $\mathbb{F}_q[A] \cong \mathbb{F}_{q_{nil}}^2$ the degenerate nilpotent case.

4. IDENTIFYING MAXIMAL COMMUTATIVE SUB-ALGEBRAS

At this point, we have shown that each matrix $A \in M_2(\mathbb{F}_q) - \mathbb{F}_q$ can be identified with the unique plane generated by taking the linear span of 1 and A, and that this plane belongs to one of three given isomorphism classes. It is reasonable to ask whether this is the maximal commutative sub-algebra of $M_2(\mathbb{F}_q)$ containing A. Indeed, if we drop the restriction of commutativity, we may easily find sub-algebras of dimension 3. The set of all upper triangular matrices is one such example.

To prove

5. PLANE COUNTS

Theorem 8. $M_2(\mathbb{F}_q)$ *has* $q^2 + q + 1$ *unique 2D commutative subalgebras.*

Proof outline notes:

- Each plane has q^2 elements.
- Each plane shares the q elements of $\mathbb{F}_q$.
- Each plane has trivial intersection.
- The planes cover all of $M_2(\mathbb{F}_q)$.

Proof. Let E_x for $x \in M_2(\mathbb{F}_q) - \mathbb{F}_q$ be the commutative subalgebra created by the span of 1 and x. Label $\Sigma = \{E_x \mid x \in M_2(\mathbb{F}_q) - \mathbb{F}_q\}$ and set $N = |\Sigma|$, the number of unique 2D commutative subalgebras. Let $x, y \in M_2(\mathbb{F}_q) - \mathbb{F}_q$. E_x, E_y are both two dimensional $\mathbb{F}_q$ algebras so we know that $E_x \cap E_y$ is also a $\mathbb{F}_q$-algebra. By dimension arguments, either $E_x = E_y$ or $E_x \cap E_y = \mathbb{F}_q$. Since $\bigcup_{E \in \Sigma} E = M_2(\mathbb{F}_q)$, $\{E_x - \mathbb{F}_q \mid x \in M_2(\mathbb{F}_q) - \mathbb{F}_q\}$ is a partition of $M_2(\mathbb{F}_q) - \mathbb{F}_q$. The following then holds,

$$N(|E_x| - |\mathbb{F}_q|) = |M_2(\mathbb{F}_q)| - |\mathbb{F}_q|$$
$$N(q^2 - q) = q^4 - q$$
$$N(q - 1) = q^3 - 1$$
$$N = q^2 + q + 1$$

$\square$

Lemma 9. *Let k be a field such that $[k : k^{\times 2}] = 2$ and $A \in M_2(k)$. Define $S = \{\det(\lambda A) \mid \lambda \in k^\times\}$.*

$$S = \begin{cases} \{0\} & \text{if } \det(A) = 0 \\ k^{\times 2} & \text{if } \det(A) \in k^{\times 2} \\ k^\times - k^{\times 2} & \text{if } \det(A) \in k^\times - k^{\times 2} \end{cases}$$

Proof. Let $A \in M_2(k)$. Then $\det(\lambda A) = \det(\lambda I) \det(A) = \lambda^2 \det(A)$ where $\lambda \in k$. If $\det(A) = 0$, then $\det(\lambda A) = 0$ for $\lambda \in k$ and $S = \{0\}$ follows. Otherwise, we know that the quotient group $k^\times / k^{\times 2}$ has only the two cosets $k^{\times 2}, k^\times - k^{\times 2}$. So if $\det(A) \in k^{\times 2}$, we have $S = \{\lambda^2 \det(A) \mid \lambda \in k^\times\} = k^{\times 2}$ and similarly, if $\det(A) \in k^\times - k^{\times 2}$, then $S = \{\lambda^2 \det(A) \mid \lambda \in k^\times\} = k^\times - k^{\times 2}$. $\square$

Lemma 10. *Consider the following elements of $M_2(\mathbb{F}_q)$.*

$$x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$
$$y = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$$

Under the conjugation action of $GL_2(\mathbb{F}_q)$ on $M_2(\mathbb{F}_q)$,

$$|\mathcal{O}_x| = q(q + 1)$$
$$|\mathcal{O}_y| = (q + 1)(q - 1)$$

Proof. We may compute the size of the orbits of x, y by first computing the size of their stabilizers, G_x, G_y, and then applying the orbit coset correspondence theorem. Now,

$$G_x = \{A \in GL_2(\mathbb{F}_q) \mid A \cdot x = x\}$$
$$= \{A \in GL_2(\mathbb{F}_q) \mid AxA^{-1} = x\}$$
$$= \{A \in GL_2(\mathbb{F}_q) \mid Ax = xA\}$$

Inevitably, matrices of the form $sx + tI$ commute with x for $s, t \in \mathbb{F}_q$, so if $sx + tI \in GL_2(\mathbb{F}_q)$, then $sx + tI \in G_x$. These are also the only possible matrices in G_x since

they are the elements of the maximal commutative subalgebra containing x requires result citation/prior inclusion. It now suffices to determine when $\det(sx + tI) = 0$.

$$\det(sx + tI) = \begin{vmatrix} t & s \\ s & t \end{vmatrix} = t^2 - s^2$$

Therefore, $\det(sx + tI) = 0$ when $t^2 = s^2$, so when $t = \pm s$. We have thus found precisely $q^2 - 2q + 1 = (q-1)^2$ elements of G_x. It follows that,

$$[GL_2(\mathbb{F}_q) : G_x] = \frac{(q^2-1)(q^2-q)}{(q-1)^2} = q(q+1)$$

By the orbit coset correspondence theorem should cite/include prior we have that $\mathcal{O}_x = q(q+1)$

Similarly we have $G_y = \{A \in GL_2(\mathbb{F}_q) | Ay = yA\}$ and the only possible elements of G_y are those of the form $sy + tI$ for $s, t \in \mathbb{F}_q$ where $sy + tI \in GL_2(\mathbb{F}_q)$.

$$\det(sy + tI) = \begin{vmatrix} t & 0 \\ s & t \end{vmatrix} = t^2$$

So $\det(sy + tI) = 0$ if and only if $t = 0$. There are then $q^2 - q$ elements of G_y. Therefore,

$$[GL_2(\mathbb{F}_q) : G_y] = \frac{(q^2-1)(q^2-q)}{q^2-q} = q^2 - 1$$

and we have $\mathcal{O}_y = q(q-1)$ ☐

Theorem 11.

(1) $$|[\mathbb{F}_{q^2}]| = \binom{q}{2}$$

(2) $$|[\mathbb{F}_q \times \mathbb{F}_q]| = \binom{q+1}{2}$$

(3) $$|[\mathbb{F}^2_{q_{nil}}]| = q + 1$$

Proof. The elements x, y from lemma 10 are the rational canonical forms for all matrices with minimum polynomials $X^2 - 1$ and X^2 respectively.

Since $X^2 - 1 = (X+1)(X-1)$ in $M_2(\mathbb{F}_q)$ and $\text{char}(\mathbb{F}_q) \neq 2$ this must be included in the introductory sections, all of the elements of $\mathcal{O}_x$ belong to an embedding of $\mathbb{F}_q \times \mathbb{F}_q$. Additionally any embedding of $\mathbb{F}_q \times \mathbb{F}_q$ must be of this form...

Now, referring to lemma 9 we know that each plane isomorphic to $\mathbb{F}_q \times \mathbb{F}_q$

By theorem 8, ... ☐
